What are twig functions?

Twig functions are reusable functions that can be called from within Twig templates to perform a specific task or return a value.

They are typically used to keep template logic simple and readable by moving more complex or reusable operations into functions. A Twig function can accept parameters, perform some processing, and return a result that can then be used in the template.

For example, you can use `{{ store_name() }}` in `twig` to output your store's name.

> See here for a list of all available twig functions, and here for how to add your own.
